## 1. The dark state

In a two-color pulse we send in light that targets two different transitions as can be seen in figure 1. The two different parts of the two-color pulse have different frequencies  $\omega_0$  and  $\omega_1$ , they also have different Rabi frequencies  $\Omega_0$  and  $\Omega_1$  as well as individual phases  $\phi_0$  and  $\phi_1$ .

If we denote the population in each level by  $c_i$  where i = 0, 1, or e; a simple rate equation can be written for the population in the excited state as:

$$\dot{c}_e = \frac{i\Omega_0}{2}e^{i\phi_0}c_0 + \frac{i\Omega_1}{2}e^{i\phi_1}c_1$$

Now assume that the incoming Rabi frequencies are the same, i.e.,  $\Omega_0 = \Omega_1 = \Omega_R$  and define  $\phi = \phi_1 - \phi_0$  and determine the state that doesn't interact with the excited level, i.e., the state  $(c_0, c_1)$ that gives  $\dot{c}_e = 0$ .

# 2. A pair of two-color pulses

As described in the lab manual a pair of two-color pulses with the same relative phase factor  $\phi$  between the two pulses within a pair, but a difference in the overall phase  $\theta$  between the two pairs, can in the  $|B\rangle$ ,  $|D\rangle$  basis be described by the operator:

$$U_{TC}^{BD} = \begin{pmatrix} e^{i\theta} & 0\\ 0 & 1 \end{pmatrix} = e^{i\theta} |B\rangle \langle B| + |D\rangle \langle D|$$

Where we have defined the bright and dark states as:

$$|B\rangle = \frac{1}{\sqrt{2}} (|0\rangle + e^{-i\phi}|1\rangle)$$
$$|D\rangle = \frac{1}{\sqrt{2}} (|0\rangle - e^{-i\phi}|1\rangle)$$

Please rewrite  $U_{TC}^{BD}$  in the  $|0\rangle$ ,  $|1\rangle$  basis, i.e.,  $U_{TC}^{01}$ .

#### 3. NOT gate

Use the results from assignment 2 to determine which  $\phi$  and  $\theta$  gives a NOT gate on the qubit levels  $|0\rangle$  and  $|1\rangle$  (neglect any global phase factor).

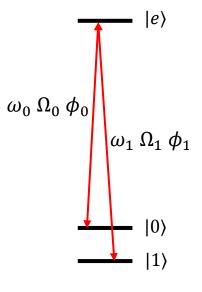

Figure 1) A three level system with two qubit levels  $|0\rangle$  and  $|1\rangle$ , and an excited state  $|e\rangle$ . Our twocolor pulse is targeting the two transitions from the two different ground levels to the excited level.

## 4. Quantum state tomography rotations

First determine for which  $\phi$  the interaction matrix,  $U_{TC}^{01}$ , corresponds to a rotation around the x and y axis, respectively (neglect any global phase factor). Then determine which combinations of  $\phi$  and  $\theta$  are needed to perform the rotations necessary to perform a quantum state tomography in all bases.

## 5. Superposition state

Choose one of the four superpositions states written below and write out which combination of  $\phi$  and  $\theta$  would bring a state initially in  $|0\rangle$  to that superposition.

$$\Psi_{a} = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$$

$$\Psi_{b} = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$$

$$\Psi_{c} = \frac{1}{\sqrt{2}}(|0\rangle + i|1\rangle)$$

$$\Psi_{d} = \frac{1}{\sqrt{2}}(|0\rangle - i|1\rangle)$$
